RECORDS OF WATER LEVELS IN WELLS IN SOUTHERN CALIFORNIA.

By F. C. EBERT.

INTRODUCTION.

SCOPE AND PURPOSE OF INVESTIGATION.

The valley of southern California, as defined by W. C. Mendenhall,¹ is the lowland region that is limited on the north by the San Gabriel Range and is separated from the Mohave and Colorado deserts on the east by the San Bernardino and San Jacinto mountains. Toward the west it is open to the Pacific, and on the south its limits are irregular and to a certain degree indefinite, the lowlands gradually giving way to the highlands of San Diego County. The wells whose records of fluctuations of water level are given in this report are chiefly in this lowland region, which includes San Bernardino Valley, the foothill belt between San Bernardino Valley and Los Angeles, the coastal plain west and south of Los Angeles, and San Jacinto Valley and adjacent areas. (See Pl. I.) A few records are also given for wells in San Diego County (pp. 126-151).

The prosperity of this important region is very largely dependent upon its ground-water resources. Most of the water supplies, whether used for domestic purposes or irrigation, are obtained wholly or in part from ground water. In 1905 Mendenhall² estimated that two-thirds of the land at that time under irrigation in this region obtained its water from subterranean sources during the protracted period of low run-off then prevailing. Since that time much more land has been brought under irrigation, and the proportion of land supplied with ground water has probably been increased.

In 1900 the United States Geological Survey began a series of studies of the occurrence, amount, distribution, and use of the ground water in the region, and published reports on the ground-water resources of San Bernardino Valley,³ the foothill belt,⁴ and the coastal

plain.⁵ A report on San Jacinto Valley and adjacent areas has recently been published.⁶ For such studies, records of the fluctuations of the water table extending over long periods are very valuable, because they show the extent of the depletion of the subterranean supply during times of light precipitation and heavy pumping and the extent of replenishment of this supply during the times of relatively heavy precipitation.

When the work was begun it was found that records of water-level fluctuations were available for only a few widely separated wells. Typical wells, properly distributed over the region under investigation, were therefore selected for observation, and measurements of the depths to the water level in these wells were made from time to time. In recent years additional wells have been selected and at least two measurements are made every year in each of the observation wells—one measurement in the spring, when the water level is generally highest, and one in the fall, when it is generally lowest. The Gage Canal Co. has furnished a record of a large number of measurements of a well known as the Williams well, near San Bernardino (see p. 121 and Pl. II), and Mr. J. B. Neff has furnished a record of measurements of his well near Anaheim (see well No. 41, p. 44, and Pl. IV).

Most of the data collected prior to 1912 have already been published⁷ in water-supply papers, but, for the convenience of those who wish to use the records, all the data are included in this report.

CAUSES OF FLUCTUATIONS OF WATER TABLE.

The supply of ground water in the valley of southern California is derived from the following sources:

1. The streams which rise in adjacent mountain regions and flow over the valley areas, where their water percolates into the underlying gravels. This is the source of most of the ground water, but, owing to the intensity of rainfall and the resulting rapid run-off in floods, much of the surface water escapes to the sea. Several methods of preventing this waste have been tried, the method most

Clapp, W. B., and Martin, W. F., Surface water supply of the United States, 1907-8, Part XI, California, prepared under the direction of M. O. Leighton: U. S. Geol. Survey Water-Supply Paper 251, pp. 338-348, 1910.

McGlashan, H. D., and Stevens, G. C., Surface water supply of the United States, 1912, Part X, Pacific coast basins in California: U. S. Geol. Survey Water-Supply Paper 331, pp. 425-434, 1914.

generally used being to increase the percolation area by spreading the flood waters over the débris cones where the streams enter the valley areas.

2. The rain which falls upon the valley areas. The amount of absorption from this source depends largely on the perviousness of the soil and underlying deposits.

3. The water applied in irrigation. During the irrigating season practically all surface water is conveyed through pipe lines or canals from the canyons to the points of application. After being applied to the land a considerable portion of the water sinks into the gravel and is added to the ground-water supply.

The supply of ground water is depleted by the following causes:

1. Pumping from wells for irrigation and domestic supply.
2. Discharge of springs and flowing wells.
3. Transpiration from vegetation.
4. Evaporation from sloughs and other low lands where the water table is near the surface.

A record of the fluctuations of the water table extending over a period of years will show the depletion and replenishment of the supply of ground water. Such a record, when studied in connection with records of precipitation and run-off, will show whether the supply, which has been depleted by superimposed draft due to increased use of ground water in addition to the natural depletion during dry years, is renewed during years of abundant rainfall. In a basin in which this does not take place either the replenishment must be increased by water spreading or other means, or else the withdrawals must be reduced by preventing waste or decreasing the pumpage. Otherwise the water table will be lowered to such a depth that it will no longer be profitable to pump the water.

GENERAL CONDITIONS SHOWN BY THE RECORDS.

To illustrate more plainly the favorable and unfavorable periods of replenishment and their effect on the ground-water level, graphs have been prepared showing precipitation, run-off, and fluctuation of the water table in the four principal areas—San Bernardino Valley, the foothill belt, the coastal plain, and San Jacinto Valley. The records of measurements during 1920 are given, but it has not been possible to bring the graphs up to date.

SAN BERNARDINO VALLEY.

San Bernardino Valley lies near the eastern end of the valley of southern California and consists of the lowlands in San Bernardino County, in the Redlands and San Bernardino quadrangles. (See Pl. I.) The hydrology of this region has been treated in Water-Supply Papers 60, 61, and 142. For this area there are several

fairly long records of water-level fluctuation, which are of interest in a study of ground-water conditions.

The principal source of ground-water replenishment is Santa Ana River and its tributaries. The Geological Survey has measured the flow of Santa Ana River near the mouth of its canyon since 1896. (See Pl. I and table below.) The longest record of precipitation in the valley is that at the city of San Bernardino, kept by the United States Weather Bureau since 1870. (See Pl. I.) The Gage Canal Co. has kept a record of the fluctuation of the water level in the Williams well, about $4\frac{1}{2}$ miles east of San Bernardino, since 1892. (See Pl. I and p. 121.)

Plate II shows the departure from the average annual precipitation at San Bernardino, the annual discharge of Santa Ana River at the mouth of its canyon, and the fluctuation of the water surface in the Williams well from observations made by the Gage Canal Co.

Observation wells Nos. 64 to 68 and 86 to 135, inclusive, are located in San Bernardino Valley. (See Pl. I.)

Discharge, in acre-feet, of Santa Ana River at mouth of canyon, entrance to San Bernardino Valley.

FOOTHILL BELT.

The foothill belt of the valley of southern California is the area eastward from the Arroyo Seco, near Pasadena, along the base of the San Gabriel Range, to the west rim of San Bernardino Valley. It includes the Cucamonga Plain and the San Gabriel Valley and the divide separating them. The Cucamonga Plain is the lowland west of San Bernardino Valley and above Santa Ana Canyon, where the river breaks through the Santa Ana Mountains. San Gabriel Valley is the area drained by San Gabriel River and its tributaries above

Paso de Bartolo except Arroyo Seco. The foothill belt is shown on the maps of the Cucamonga, Pomona, and Pasadena quadrangles. (See Pl. I.)

The principal source of ground water is the upper San Gabriel drainage basin. Important secondary sources are San Antonio, San Dimas, and other streams draining southwest from the San Gabriel Mountains. The United States Geological Survey has maintained a gaging station at the mouth of San Gabriel River Canyon since 1896. (See Pl. I.) The resulting discharge data, given in the table below, and the record of precipitation for Los Angeles, which has been kept since 1877, show the favorable and unfavorable years for augmenting subterranean storage. Hence, a comparison of these two records with the fluctuation of the water level in well No. 42 (p. 47), at Baldwin Park, is of interest. (See Pl. III.)

Observation wells Nos. 23 to 33 and 42 to 63a. inclusive are located in the foothill belt. (See Pl. I.)

Discharge, in acre-feet, of San Gabriel River near Azusa, Calif.

COASTAL PLAIN.

The coastal plain has an area of approximately 775 square miles. It consists of the lands between the Santa Monica Mountains and the San Joaquin Hills and extends from the Santa Ana Mountains and Puente Hills to the Pacific. The drainage consists of Santa Ana River below the lower Santa Ana Canyon, San Gabriel River below Paso de Bartolo, Los Angeles River, and Santiago Creek. The region is shown on the maps of the Santa Monica, Redondo, Downey, Las Bolsas, Santa Ana, and Anaheim quadrangles. (See Pl. I.)

The principal sources of ground water in this area are the flood waters of the streams that traverse the area. Plate IV shows the

fluctuation of the water level in well No. 41, based on a record kept by the owner, Mr. J. B. Neff (see p. 44), and the variation of the annual precipitation at the Irvine ranch, near Tustin. (See Pl. I.) No gaging stations are maintained within the area, but the run-off records of Santa Ana River and San Gabriel River (see Pl. I and pp. 8, 9) are applicable in comparing the causes of replenishment and depletion of ground-water supply as shown by the fluctuations of the water table.

Observation wells Nos. 1 to 22c and 34 to 41, inclusive, are in the Coastal Plain. (See Pl. I.)

SAN JACINTO VALLEY. •

San Jacinto Valley is the lowland area in the San Jacinto River drainage basin above Railroad Canyon, which is a few miles southwest of Perris. The region is shown on the maps of the San Jacinto and Elsinore quadrangles. (See Pl. I.)

The replenishment of ground water in this valley is largely by percolation from San Jacinto River during periods of high water, but, owing to the low permeability of the soils, the percolation is slow.

That there is an overdraft in some portions of the valley is indicated by figure 1, which shows the fluctuation at well No. 72 (see p. 75), and the departure from the average annual precipitation at San Jacinto. (See Pl. I.) It will be noted that in spite of favorable precipitation in the past four years the water table has been constantly lowered.

Observation wells Nos. 69 to 85a, inclusive, are in San Jacinto Valley. (See Pl. I.)

EXPLANATION OF RECORDS.

In 1900 Lippincott made measurements of the depth to the water level in approximately 900 wells in San Bernardino Valley.⁸ In 1904 Mendenhall measured the same wells.⁹ A large number of these wells have never since been measured by the United States Geological Survey and are not considered herein. At a few wells, however, measurements have been made at irregular intervals, and these measurements are included in this report. In 1913 the wells still in existence and a few companion wells were given new numbers (Nos. 86 to 135, inclusive), and are designated by these new numbers in the following tables. Data collected prior to 1913 from the wells which had been destroyed or were inaccessible in 1913 are published in a separate table (p. 120) under the numbers by which they are designated in Water-Supply Paper 142.

⁸ Lippincott, J. B., Development and application of water near San Bernardino, Colton, and Riverside, Calif., Part II: U. S. Geol. Survey Water-Supply Paper 60, pp. 97-141, 1902.

⁹ Mendenhall, W. C., The hydrology of San Bernardino Valley, Calif.: U. S. Geol. Survey Water-Supply Paper 142, 124 pp. 12 pls., 1905.

In addition to these wells in San Bernardino Valley, Mendenhall, on the commencement of his studies of ground water in the valley of southern California in 1904, selected for observation a series of wells located in the coastal plain, foothill belt, and San Jacinto Valley. These wells, which are designated as wells Nos. 1 to 85, inclusive, were considered more or less typical for these important ground-water districts. The water levels in them were measured at irregular intervals prior to 1913 and have been measured more regularly since 1913.

FIGURE 1.—Graphs showing fluctuation of water level in well No. 72, in San Jacinto Valley, Calif., together with precipitation at San Jacinto.

For each well in the series now under observation (Nos. 1 to 135, inclusive) is given the owner's name, the location, and other available information. The location of each well is shown on the map (Pl. I). For most of the wells is also given a description of the bench mark from which the distance to the water level is measured. The altitudes given for many of the wells from Nos. 1 to 85, inclusive, are the approximate altitudes of the surface of the ground at the wells; the

altitudes of bench marks of wells Nos. 86 to 135, inclusive, were determined by instrumental leveling and are believed to be accurate. For wells Nos. 86 to 135, inclusive, the bench marks described were not located until 1914, and all measurements prior to this date were made from the surface of the ground. Most of the wells have been described in earlier water-supply papers, and references to these papers are given under these wells.

In order to perpetuate the series, companion wells are being chosen, wherever possible, for wells in bad repair.

Observations of the pressure of a few flowing wells in San Bernardino Valley have also been started, and the data thus far obtained are given on pages 117-119.

THE RECORDS.

VALLEY OF SOUTHERN CALIFORNIA.

Records of water levels in the valley of southern California.

1. Richard Kidson, corner Forty-ninth and Main streets, Los Angeles, Redondo quadrangle.

[Bored well, 52 feet deep, 7 inches in diameter; sunk about 1874; elevation of surface, about 165 feet above sea level; method of lift, wind; use, domestic. Water contains 840 parts per million of dissolved solids, Bench mark from which measurements were made is not known. Well No. 848, Water-Supply Paper 139, p. 94.]

28a. G. B. Renfro, three-fourths mile southwest of Savannah, Pasadena quadrangle.

[Dug well, 5 feet in diameter for 24 feet, then 12-inch bore for 63 feet. Method of lift, wind and gasoline engine; use, irrigation and domestic; situated 50 feet south of well No. 28. Bench mark: Originally bottom of a 10 by 10 inch timber across curb, 4 inches below surface. Between May 26, 1917, and May 11, 1918, the 10 by 10 inch timber was removed. A new bench mark was established as the top of the west side of the curb, about 1 foot 4 inches higher than the original bench mark. An addition of 1 foot 4 inches has been made to all measurements previous to May 11, 1918, to make them comparable with measurements from the present bench mark.]

SAN DIEGO COUNTY.

In addition to the records of wells in the valley of southern California, records are given below for a few wells in the western part of San Diego County. Observations on the water levels in wells in that region were begun in 1912 by Arthur J. Ellis and Charles H. Lee. The data for many of these wells for the years 1912 to 1915 were published in Water-Supply Paper 446, in the form of diagrams showing graphically the fluctuations of the water table. Many wells that were measured during that period were destroyed by the floods in January, 1916. In the present report the basic data for all wells that are still being measured are given complete since 1912, and data for a few new wells are included. The numbers correspond to those in Water-Supply Paper 446.
